

HCI Focus — Adobe After Effects

Interaction elements used to control and inspect a 3D scene

① Tools Panel

The selection, hand, rotation, and camera-orbit tools sit at the top of the window, giving the user direct mouse control over the 3D view instead of typed commands.

② Timeline Layer Controls

Icon columns per layer (visibility, lock, shy) let the user toggle what's editable or visible at a glance, without digging through menus.

③ Position Property Field

Live numeric X/Y/Z values update as the layer moves, giving immediate feedback that confirms the action and allows precise manual entry.

CG Focus — Adobe After Effects

Rendering elements that construct the illusion of 3D space

① Light Source & Shadow Falloff

A single light produces a specular highlight and gradient shading across the sphere, giving it volume instead of a flat silhouette.

② Camera Perspective / Frustum

The lines converging to a single vanishing point define the camera's field of view, which is what makes the flat screen read as receding 3D space.

③ 3D Mesh / Orbit Guides

The wireframe rings around the sphere trace its underlying spherical geometry, showing how the curved surface is defined in 3D space.

Reflection

1. Does CG quality help or hinder interaction? The shading and perspective make depth and object placement easy to read at a glance, which helps precise 3D positioning. But denser scenes with ray-traced shadows can slow the viewport, making orbiting and editing feel sluggish.

2. One HCI improvement: Add a small on-screen readout of the current camera angle/view name, so users don't lose track of orientation while orbiting freely around the scene.
